Abstract. Given four (distinct) lines $\ell_1, \ell_2, \ell_3, \ell_4$ in $\mathbb{P}^3$. Let $P_i (i = 1, \ldots, 4)$ be the image of $\ell_i$ in the Plücker’s quadric $\mathcal{Q} \subset \mathbb{P}^5$ under the Plücker embedding $\mathcal{P}$ (in (1)). Set $\Lambda = \langle P_1, \ldots, P_4 \rangle$ be the linear span of those four points in $\mathbb{P}^5$. The purpose of this article is to write specifically what kind of quadric $\Lambda \cap \mathcal{Q}$ can be, taking under considerations all possible configurations of these four lines in $\mathbb{P}^3$. In particular, having in mind the classical problem in Schubert Calculus: How many lines in 3-space meet four given lines in general position? whose answer is 2 (see p. 272 in [3] or p. 746 in [4]). We verified that four lines in $\mathbb{P}^3$ are in general position if and only if $\Lambda$ is a 3-plane and $\Lambda \cap \mathcal{Q}$ is an irreducible quadric surface. In fact, we prove that there are exactly two solutions if and only if $\Lambda$ is a 3-plane and $\Lambda \cap \mathcal{Q}$ is a nonsingular quadric.

2010 Mathematics Subject Classifications: AMS 14N05, 14N20
Key Words and Phrases: Plücker's quadric, linear span, 4-line problem.

1. Introduction

Plücker’s coordinates were introduced by the German geometer Julius Plücker (1801-1868) in the 19th century, as a way to assign six homogenous coordinates to each line in the complex projective 3-space $\mathbb{P}^3$. Since they satisfy a homogeneous quadratic equation, it follows an embedding of the 4-dimensional space of lines in $\mathbb{P}^3$ (denoted by $\mathbb{G}_1(\mathbb{P}^3)$ and called grassmannian of lines in $\mathbb{P}^3$) onto a nonsingular quadric hypersurface $\mathcal{Q}$ in $\mathbb{P}^5$ (see Proposition 3). Thus, reminding the Schubert’s classical enumerative problem: How many lines in 3-space meet four given lines in general position? Whose answer can be found in many texts and is given by: “there are two lines in $\mathbb{P}^3$ which meet 4 given lines in general position” (see Example 14.7.2 at p. 272 in [3]). In fact, if you want to know an algorithm to determine explicit solutions, then see [7]. On the other hand, any beginner in the art of solving enumerative problems will ask: what does general position means? In Algebraic Geometry, general position is a notion of genericity for a set of points, or other geometric objects. It means the
general case situation, as opposite to some more special or coincident cases that are possible. Its precise meaning differs in different settings. For example, in [8] the authors imposed the condition $\ell_i \cap \ell_j = \emptyset$ (1 \leq i < j \leq 4) to the four given lines $\ell_1$, $\ell_2$, $\ell_3$, $\ell_4$ in $\mathbb{P}^3$ and, even under this assumption they found (in one case) infinitely many solutions for the 4-lines problem (cf. 3.1 in the last subsection). So, this condition is not enough for the four given lines to be in general position.

In this article, we use the identification between lines in $\mathbb{P}^3$ and points in the quadric hypersurface $\mathcal{Q}$ to explain what is the precise meaning of general position for that problem. Nevertheless, the emphasis in our work lies on to take under considerations all possible configurations of these four lines in $\mathbb{P}^3$ and write specifically what kind of quadric $\Lambda \cap \mathcal{Q}$ can be. One key ingredient in this work lies on the well known description of all linear subspaces contained in a quadric hypersurface in $\mathbb{P}^3$ and $\mathbb{P}^5$ (see subsection 2.1 and 3.1).

Finally, we note that Plücker was a geometer that firmly believed in the importance of the applications of Mathematics to the physical sciences. So, in 1847 he turned to Physics, accepting the chair of Physics at Bonn and working on magnetism, electronics and atomic physics. He anticipated Gustav Kirchhoff and Robert Wilhelm Bunsen in announcing that the lines of the spectrum were characteristic of the chemical substance which emitted them, and in indicating the value of this discovery in chemical analysis. According to Johann Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances.

2. Notations and Preliminary Results

We denote by $\mathbb{C}$ the field of complex numbers. Let $V$ be an $n$-dimensional vector space over $\mathbb{C}$. Denote by $[v_1, \ldots, v_k]$ the subspace of $V$ generated by the vectors $v_1, \ldots, v_k \in V$.

The $k$-grassmannian associated to the vector space $V$. For each integer $k$, $0 \leq k \leq n = \dim V$, we denote by $G_k(V)$ the set of all $k$-dimensional linear subspaces of $V$ and call it the $k$-grassmannian associated to $V$. In the particular case $k = 1$, the 1-grassmannian associated to $V$ it is also called projective space associated to $V$ and it is denoted by $\mathbb{P}(V)$ (i.e. $\mathbb{P}(V) := G_1(V)$). We use the notation $\mathbb{P}^n$ instead of $\mathbb{P}(\mathbb{C}^{n+1})$ and $p = [a_0 : \ldots : a_n]$ for $p = [(a_0, \ldots, a_n)] \in \mathbb{P}^n$, just for the sake of simplicity.

If $W \in G_{k+1}(V)$ then $\mathbb{P}(W) \subseteq \mathbb{P}(V)$ will be called $k$-linear subspace of $\mathbb{P}(V)$. The set of all $k$-linear subspaces of $\mathbb{P}(V)$ will be denoted by $G_k(\mathbb{P}(V))$, the grassmannian of $k$-linear subspaces of $\mathbb{P}(V)$. Moreover, we shall call $G_1(\mathbb{P}(V))$, $G_2(\mathbb{P}(V))$ and $G_{n-1}(\mathbb{P}(V))$ the grassmannian of lines, planes and hyperplanes in $\mathbb{P}(V)$, respectively. So, since a line $\ell$ in $\mathbb{P}^3$ is equal to $\mathbb{P}(W)$ for some $W \in G_2(\mathbb{C}^4)$, we have the correspondence

$$
G_2(\mathbb{C}^4) \quad \longrightarrow \quad G_1(\mathbb{P}^3)
$$

$$
W \quad \longmapsto \quad \mathbb{P}(W)
$$

between the 2-grassmannian associated to $\mathbb{C}^4$ and the grassmannian of lines in $\mathbb{P}^3$. Thus, all assertions involving $G_2(\mathbb{C}^4)$ can be translated into $G_1(\mathbb{P}^3)$. 
Next we introduce the notion of algebraic projective set in $\mathbb{P}^n$. We will see in Proposition 1 that $k$-linear subspaces of $\mathbb{P}^n$ are examples of algebraic sets.

**Algebraic projective sets in $\mathbb{P}^n$.** Let $\mathbb{C}[X] = \mathbb{C}[X_0, \ldots, X_n]$ be the polynomial ring over $\mathbb{C}$ in the variables $X_0, \ldots, X_n$. Now, for each integer $d \geq 0$ consider the vector subspace $\mathbb{C}[X]_d$, generated by all monomials in $X_0, \ldots, X_n$ of degree $d$. Each element in $\mathbb{C}[X]_d$ will be called an homogeneous polynomial of degree $d$. If $F \in \mathbb{C}[X]_d$, then we define, $\mathcal{Z}(F)$, the zero set of $F$ in $\mathbb{P}^n$ by

$$\mathcal{Z}(F) = \{(v) \in \mathbb{P}^n | F(v) = 0\}.$$ 

For example, if $L \in \mathbb{C}[X]_1$, then $\mathcal{Z}(L) = \mathbb{P}(W)$ with $W = \{v \in \mathbb{C}^{n+1} | L(v) = 0\}$. Therefore, $\mathcal{Z}(F)$ is a hyperplane of $\mathbb{P}^n$, if $L \neq 0$ else $\mathcal{Z}(F) = \mathbb{P}^n$.

If $d \geq 1$, then an element $[F]$ in the projectivization of $\mathbb{C}[X]_d$ will be called **hypersurface of degree** $d$ in $\mathbb{P}^n$. From here on, when we say: Let $X \subset \mathbb{P}^n$ be the reduced hypersurface defined by $F \in \mathbb{C}[X]_d$, that means that $X = \mathcal{Z}(F) \subset \mathbb{P}^n$ and $F$ is square-free.

A subset $X$ of $\mathbb{P}^n$ will be called **algebraic projective set**, if there exist homogeneous polynomials $F_1, \ldots, F_k$ in $\mathbb{C}[X]$ such that $X = \mathcal{Z}(F_1) \cap \cdots \cap \mathcal{Z}(F_k)$.

Next we show that any $r$-linear subspace in $\mathbb{P}^n$ is the intersection of exactly $n-r$ hyperplanes.

**Proposition 1.** Let $\Lambda$ be an $r$-linear subspace in $\mathbb{P}^n$ with $n > r$. Then, there are exactly $n-r$ linearly independent linear forms $L_1, \ldots, L_{n-r}$ in $\mathbb{C}[X]$ such that

$$\Lambda = \mathcal{Z}(L_1) \cap \cdots \cap \mathcal{Z}(L_{n-r}).$$

**Proof.** Assume that $\Lambda = \mathbb{P}(W)$ with $W \in G_{r+1}(\mathbb{C}^{n+1})$. Let $\alpha = \{e_1, \ldots, e_{n+1}\}$ be the canonical base of $\mathbb{C}^{n+1}$ and let $\beta = \{e_1^*, \ldots, e_{n+1}^*\}$ be the associated dual base of $(\mathbb{C}^{n+1})^*$. Next we consider the linear isomorphism

$$\varphi : (\mathbb{C}^{n+1})^* \rightarrow \mathbb{C}[X]_{-1} \quad e_i^* \rightarrow X_{i-1}.$$ 

Now, let $W^0$ be the annihilator of $W$, then $\varphi(W^0)$ is an $(n-r)$-dimensional linear subspace of $\mathbb{C}[X]_{-1}$. Finally, an easy verification show that any base $\{L_1, \ldots, L_{n-r}\}$ of $\varphi(W^0)$ verified that $\Lambda = \mathcal{Z}(L_1) \cap \cdots \cap \mathcal{Z}(L_{n-r})$. 

**Incidence of $r$-linear subspaces with reduced hypersurfaces in $\mathbb{P}^n$.** The following proposition will play an important role in our investigations.

**Proposition 2.** Let $Z \subset \mathbb{P}^n$ be the reduced hypersurface defined by the homogeneous polynomial $F$ of degree $d$ and $\Lambda$ be an $r$-linear subspace of $\mathbb{P}^n$ with $r \geq 1$. Then the following conditions are verified.
(1) $Z \cap \Lambda \neq \emptyset$;

(2) $Z \cap \Lambda$ consists of infinitely many points, if $\Lambda \subset Z$ or $r \geq 2$, else $Z \cap \Lambda$ consists of at most $d$ points.

Proof. To arrive at statements (1) and first part of (2) have in mind that $\dim Z = n - 1$, $\dim \Lambda = r$ and apply Theorem 7.2 at p. 48 in [5]. Already, the last part of statement (2) follows easily from the fundamental theorem of algebra.

**Projective Tangent Space and Nonsingular Reduced hypersurface.** Let $Z \subset \mathbb{P}^n$ be the reduced hypersurface defined by $F \in \mathbb{C}[X]_d$ and $p = [v] \in Z$. Let $F'_v : \mathbb{C}^{n+1} \rightarrow \mathbb{C}$ be the differential of $F$ at $v$. We define the **projective tangent space**, $T_pZ$, to the hypersurface $Z$ at $p$ by

$$T_pZ = \mathbb{P}(\ker(F'_v)) = \{[u_0 : \ldots : u_n] \in \mathbb{P}^n | \sum_{i=0}^n \frac{\partial F}{\partial X_i}(v) \cdot u_i = 0\}.$$ 

Now, note that:

- follows from the Euler relation $\sum_{i=0}^n \frac{\partial F}{\partial X_i} \cdot X_i = dF$ that $p \in T_pZ$.

- $T_pZ$ is a hyperplane in $\mathbb{P}^n$ if and only if $p \notin \cap_{i=0}^n \mathcal{Z}(\frac{\partial F}{\partial X_i}).$

A point $p \in Z$ satisfying the last condition above will be called a **nonsingular point** of $Z$, else $p$ will be called a **singular point** of $Z$. If all the points in $Z$ are nonsingular, then $Z$ will be called a **nonsingular** hypersurface in $\mathbb{P}^n$.

For example, after a linear change of coordinates (see Theorem 4 at p. 411 in [2]) we concluded that $\mathcal{Z}(X_0^2 + X_1^2 + X_2^2 + X_3^2)$ is the unique nonsingular quadric surface in $\mathbb{P}^3$, whereas the singular reduced quadric surfaces in $\mathbb{P}^3$ correspond either to the union of two planes or a quadric cone. Moreover, it is straightforward to show that the vertex of a quadric cone is its unique singular point. In the case of the union of two (distinct) planes, it is verified that the points in the line where the two planes meet are their singular points.

### 2.1. Lines on Reduced Quadrics Surfaces in $\mathbb{P}^3$

Next, we present some observations about lines contained on reduced quadrics surfaces in $\mathbb{P}^3$.

- **Union of two planes.** Of course any line in this surface will be contained in one of the planes. Thus this surface could have at most two disjoint lines.

- **Quadric cone.** Any line in this surface passes through its vertex. Thus this surface does not contain disjoint lines.

- **The nonsingular quadric surface.** As we shall describe in the next Lemma, a nonsingular quadric surface in $\mathbb{P}^3$ contains exactly two families of lines parametrize by $\mathbb{P}^1$. In fact, this Lemma is part of exercise 2.15 in Hartshorne’s book [5]. See the proof at p. 478-479 in [4] or [8].
Lemma 1. Let $Q$ be a nonsingular quadric surface in $\mathbb{P}^3$. Then there exist two families of lines $\mathcal{L} = \{L_p\}_{p \in \mathbb{P}^1}$ and $\mathcal{M} = \{M_p\}_{p \in \mathbb{P}^1}$ in $Q$ such that

1. $L_p \cap L_q = \emptyset$ and $M_p \cap M_q = \emptyset$ for all $L_p, L_q \in \mathcal{L}$, $M_p, M_q \in \mathcal{M}$ and $p \neq q \in \mathbb{P}^1$. 

2. $L_p \cap M_q \neq \emptyset$ for all $L_p \in \mathcal{L}$, $M_q \in \mathcal{M}$ and $p, q \in \mathbb{P}^1$. 

3. If $\ell$ is a line contained in $Q$ then $\ell \in \mathcal{L}$ or $\ell \in \mathcal{M}$. 

4. Given $x \in Q$ there exist unique lines $L_{p(x)} \in \mathcal{L}$ and $M_{q(x)} \in \mathcal{M}$ such that $\{x\} = L_{p(x)} \cap M_{q(x)}$. 

One other simple but important fact which will help us to prove our main result (Theorem 1) is the next Lemma.

Lemma 2. Given the lines $\ell_1$, $\ell_2$ and $\ell_3$ in $\mathbb{P}^3$ such that $\ell_i \cap \ell_j = \emptyset$ for $1 \leq i < j \leq 3$, there exists a nonsingular quadric surface $Q$ in $\mathbb{P}^3$ containing $\ell_1$, $\ell_2$ and $\ell_3$. 

Proof. Take 3 points $p_{1i}$, $p_{2i}$, $p_{3i}$ on each line $\ell_i$ ($i = 1, 2, 3$) and note that 

$$W = \{G \in \mathbb{C}[X]_2 \mid G(p_{ij}) = 0 \text{ for all } 1 \leq i, j \leq 3\} \text{ (here } n = 3)$$

is a subspace of $\mathbb{C}[X]_2$ of dimension greater than or equal to 1. So we can choose $G \neq 0$ in $W$ and take $Q = \mathcal{P}(G)$. Now follows from Proposition 2 that each line $\ell_i$ is contained in $Q$. Finally, since $Q$ contains three pairwise disjoint lines, then $Q$ must be a nonsingular surface in $\mathbb{P}^3$. \qed

3. The Plücker’s Quadric $\mathcal{Q}$ in $\mathbb{P}^5$

The Plücker embedding $\mathcal{P} : G_1(\mathbb{P}(V)) \longrightarrow \mathbb{P}(\Lambda^{k+1}V)$ is the map that enable us to identify the grassmannian $G_k(\mathbb{P}(V))$ with a projective variety in $\mathbb{P}(\Lambda^{k+1}V)$ ($\Lambda^{k+1}V$ denotes the $(k+1)$-th exterior power of $V$). It is defined by $\mathbb{P}(W) \mapsto [u_0 \wedge \ldots \wedge u_k]$, if $W = [u_0, \ldots, u_k]$. 

The Plücker’s quadric $\mathcal{Q}$ in $\mathbb{P}^5$. In what follows we will consider $V = \mathbb{C}^4$. Now, fix the base $\{e_i \wedge e_j\}_{1 \leq i < j \leq 4}$ of $\Lambda^2 \mathbb{C}^4$ where $\{e_i\}_{i=1}^4$ is the canonical basis of $\mathbb{C}^4$. Let us consider $W = [u, v] \in G_2(\mathbb{C}^4)$ with $u = (u_0, u_1, u_2, u_3)$ and $v = (v_0, v_1, v_2, v_3)$, then we see that 

$$u \wedge v = \sum_{1 \leq k < l \leq 4} w_{k-1,l-1} e_k \wedge e_l \text{ where } w_{ij} = u_i v_j - u_j v_i \text{ for } 0 \leq i < j \leq 3.$$ 

Thus the Plücker embedding $\mathcal{P}$ above in coordinates is given by 

$$\mathcal{P} : G_1(\mathbb{P}^3) \longrightarrow \mathbb{P}^5,$$

$$\mathbb{P}([u, v]) \longrightarrow [w_{01} : w_{02} : w_{03} : w_{12} : w_{13} : w_{23}].$$

(1)

Proposition 3. The Plücker map $\mathcal{P} : G_1(\mathbb{P}^3) \longrightarrow \mathbb{P}^5$ defined in (1) is an embedding of the grassmannian $G_1(\mathbb{P}^3)$ over the nonsingular quadric hypersurface $\mathcal{Q} = \mathcal{Q}(F) \subset \mathbb{P}^5$ where 

$$F = X_0 X_5 - X_1 X_4 + X_2 X_3 \in \mathbb{C}[X](n = 5).$$
Let $Z\subset\mathbb{P}^n$ be a nonsingular quadric hypersurface defined by $G \in \mathbb{C}[X]_2$ and $\Lambda$ a $r$-linear subspaces of $\mathbb{P}^n$. Assume that $G = \sum_{i=0}^{n} X_i^2$ (otherwise make a linear change of coordinates). So $G$ induz the bilinear form $B : \mathbb{C}^{n+1} \times \mathbb{C}^{n+1} \to \mathbb{C}$ given by $B(v, w) = v_0 w_0 + \cdots + v_n w_n$, if $v = (v_0, \ldots, v_n)$ and $w = (w_0, \ldots, w_n)$. Let

$$W^\perp = \{ v \in \mathbb{C}^{n+1} \mid B(v, w) = 0 \text{ for all } w \in W \}$$

be the orthogonal subspace associated to $W$.

Note that $W^\perp = \ker(T_i) \cap \cdots \cap \ker(T_r)$ where $T_i$ is the linear functional over $\mathbb{C}^{n+1}$ given by $T_i(v) = B(v, w_i)$, $i \in \{0, \ldots, r\}$. Since these linear functionals are linearly independent we conclude that $\dim W^\perp = n + 1 - \dim W = n - r$.

On the other hand, $\Lambda \subset Z$ if and only if $G(w) = B(w, w) = 0$ for all $w \in W$. Thus $\Lambda \subset Z$ if and only if $W \subset W^\perp$. So, if $\Lambda \subset Z$ then $\dim W \leq \dim W^\perp = n + 1 - \dim W$. Therefore, $2 \dim W \leq n + 1$ which implies $2r < n$. 

In what follows, we denoted by $\langle \ell_1, \ldots, \ell_k \rangle$ the smallest linear subspace of $\mathbb{P}^n$ containing the lines $\ell_1, \ldots, \ell_k$ of $\mathbb{P}^n$. For example, if $\ell_1$ and $\ell_2$ are two distinct lines in $\mathbb{P}^n$ having a common point, then $\langle \ell_1, \ell_2 \rangle$ is a plane, else $\langle \ell_1, \ell_2 \rangle$ is a 3-plane.

Next we give the description of lines and planes in $\mathcal{Q}$.

**Lines in the Plücker’s quadric $\mathcal{Q}$**. The lines in the Plücker’s quadric $\mathcal{Q}$ are parametrized by the incidence variety $\Gamma = \{(p, \Pi) \mid p \in \Pi \} \subset \mathbb{P}^3 \times G_2(\mathbb{P}^3)$. In fact, let $p \in \mathbb{P}^3$ and $\Pi \subset \mathbb{P}^3$ be a plane through $p$. Set

$$\Omega_p(\Pi) = \{ \ell \in G_1(\mathbb{P}^3) \mid p \in \ell \subset \Pi \}.$$
Proposition 5. Let $\mathcal{P} : \mathbb{G}_1(\mathbb{P}^3) \rightarrow \mathbb{P}^5$ be the Plücker embedding in (1). If $L$ is a line in $\mathbb{P}^5$ contained in $\mathcal{L}$, then we have:

(i) $\mathcal{P}(\Omega_p(\Pi))$ is a line in $\mathbb{P}^5$ contained in $\mathcal{L}$ for all $(p, \Pi) \in \Gamma$.

(ii) If $P_0, P \in L$ are two different points such that $P_0 = \mathcal{P}(\ell_0)$ and $P = \mathcal{P}(\ell)$, then $\ell_0 \cap \ell = \{p\}$ and they determine the plane $\Pi = \langle \ell_0, \ell \rangle$. In fact, for every point $Q = \mathcal{P}(m) \in L$ holds that $m \in \Omega_p(\Pi)$.

Planes in the Plücker’s quadric $\mathcal{L}$. There are two families of planes in the Plücker’s quadric $\mathcal{L}$ parametrized by $\mathbb{P}^3$ and its dual $\mathbb{P}^3 = \mathbb{G}_2(\mathbb{P}^3)$, respectively. In fact, let $p \in \mathbb{P}^3$ and $\Pi \subset \mathbb{P}^3$ be a plane. Set

$$\Omega_p = \{ \ell \in \mathbb{G}_1(\mathbb{P}^3) \mid p \in \ell \}$$

and

$$\Omega(\Pi) = \{ \ell \in \mathbb{G}_1(\mathbb{P}^3) \mid \ell \subset \Pi \}.$$

Proposition 6. Let $\mathcal{P} : \mathbb{G}_1(\mathbb{P}^3) \rightarrow \mathbb{P}^5$ be the Plücker embedding in (1). If $\Lambda$ is a plane in $\mathbb{P}^5$ contained in $\mathcal{L}$, then we have:

(i) $\mathcal{P}(\Omega_p)$ and $\mathcal{P}(\Omega(\Pi))$ are planes in $\mathbb{P}^5$ contained in $\mathcal{L}$.

(ii) The pre-image of $\Lambda$ under the Plücker embedding $\mathcal{P}$ is either: $\Omega_p$ for some $p \in \mathbb{P}^3$ or $\Omega(\Pi)$ for some $\Pi \in \mathbb{G}_2(\mathbb{P}^3)$. In fact, if $P_i = \mathcal{P}(\ell_i)$, $i = 0, 1, 2$ are three points in $\mathcal{L}$ whose linear span it is equal to $\Lambda$, then $\Lambda = \Omega_p$ if $p \in \cap_{i=0}^2 \ell_i$ (and these lines are non-coplanar) else $\Lambda = \Omega(\Pi)$ with $\Pi = \langle \ell_0, \ell_1, \ell_2 \rangle$.

4. Description of $\Lambda \cap \mathcal{L}$ According to the Relative Position of the Four Given Lines in $\mathbb{P}^3$

We begin this section by introducing some more notation. As we did for lines we denote by $(p_1, \ldots, p_k)$ the linear span of $p_1, \ldots, p_k \in \mathbb{P}^n$ (i.e. the smallest linear subspace of $\mathbb{P}^n$ containing these points). Moreover, if $p$ is a point and $\ell$ is a line in $\mathbb{P}^n$, then $(p, \ell)$ also denote the linear span of $p$ and $\ell$ in $\mathbb{P}^n$. So $(p, \ell) = \ell$, if $p \in \ell$ else $(p, \ell)$ is a 3-plane.

Let $\ell_1, \ell_2, \ell_3$ and $\ell_4$ be four distinct lines in $\mathbb{P}^3$. Let $P_i \in \mathcal{L}$ $(i = 1, \ldots, 4)$ be the image of $\ell_i$ under the Plücker embedding $\mathcal{P}$ in (1) and $\Lambda = \{P_1, P_2, P_3, P_4\} \subset \mathbb{P}^5$. Set $\mathcal{S}$ be the set of solutions of the 4-lines problem in Schubert calculus, i.e.

$$\mathcal{S} = \{ \ell \in \mathbb{G}_1(\mathbb{P}^3) \mid \ell \cap \ell_i \neq \emptyset \text{ for } 1 \leq i \leq 4 \}.$$

We have three major cases to be considered (cf. subsections 4.1, 4.2 and 4.3). In each of these cases, the linear space $\Lambda$ and $\Lambda \cap \mathcal{L}$ are reported in tables, whose rows are labeled according to the position that the lines can have in $\mathbb{P}^3$. Next, we determine $\Lambda$ and $\Lambda \cap \mathcal{L}$ in some of these cases, which we believe are sufficient to illustrate the technique used in this computations, we left to the reader the other cases.

In what follows, for simplicity, we will use the notation $\Omega_p(\Pi)$, $\Omega_p$ and $\Omega(\Pi)$ for lines and planes in $\mathcal{L}$, according to the identification given by the Plücker embedding in Propositions 5 and 6, respectively.
4.1. The Four Lines are Concurrent, Say $p \in \cap_{i=1}^{4} \ell_i$.

Table 1: Four Lines are Concurrent.

<table>
<thead>
<tr>
<th>Subcase</th>
<th>Position of the lines</th>
<th>$\mathcal{S}$</th>
<th>$\Lambda$</th>
<th>$\Lambda \cap \mathcal{Q}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.1</td>
<td>$\ell_1, \ell_2, \ell_3$ and $\ell_4$ are contained in the plane $\Pi$</td>
<td>$\Omega_p \cup \Omega(\Pi)$</td>
<td>Line</td>
<td>$\Omega_p(\Pi)$</td>
</tr>
<tr>
<td>1.2</td>
<td>$\ell_1, \ell_2, \ell_3$ and $\ell_4$ are non coplanar lines</td>
<td>$\Omega_p$</td>
<td>Plane</td>
<td>$\Omega_p$</td>
</tr>
</tbody>
</table>

1.1 Naturally any line passing through $p$ is a solution. On the other hand, if $\ell \in \mathcal{S}$ is a solution such that $p \notin \ell$, it certainly meets the lines $\ell_1$ and $\ell_2$ at two different points, which implies that $\ell \subset \Pi$. Therefore $\mathcal{S} = \Omega_p \cup \Omega(\Pi)$. On the other hand, since $P_i \in \Omega_p(\Pi)$ for $i = 1, \ldots, 4$, then $\Lambda \equiv \Omega_p(\Pi)$ is a line contained in $\mathcal{Q}$.

![Figure 1: Case 1.1](image)

4.2. The Four Lines have no Common Point and at Least Two are Coplanar.

Of course in all the subcases listed below we consider an index reordering if necessary.

Table 2: Four Lines have no Common Point and at Least Two are Coplanar.

<table>
<thead>
<tr>
<th>Subcase</th>
<th>Position of the lines</th>
<th>$\mathcal{S}$</th>
<th>$\Lambda$</th>
<th>$\Lambda \cap \mathcal{Q}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.1</td>
<td>$\ell_1, \ell_2, \ell_3$ and $\ell_4$ are contained in the plane $\Pi$</td>
<td>$\Omega(\Pi)$</td>
<td>Plane</td>
<td>$\Omega(\Pi)$</td>
</tr>
</tbody>
</table>

2.1 Of course any line contained in the plane $\Pi$ is a solution. Now, since the four given lines have not common point, then any solution will meets at least two of these at different points. Therefore, $\mathcal{S} = \Omega(\Pi)$. Now, since the four lines are not concurrent, then three of these four points (the $P_i$’s) determine the plane $\Omega(\Pi)$. In fact, $\Lambda \equiv \Omega(\Pi)$, so it is a plane contained in $\mathcal{Q}$.
Table 3: 2.2 Exactly Three Lines are Coplanar. Assume that \( \ell_1, \ell_2, \) and \( \ell_3 \) are contained in the plane \( \Pi \) and \( \Pi \cap \ell_4 = \{q\} \).

<table>
<thead>
<tr>

2.2.1 Let \( \ell \in \mathcal{S} \) be a solution which meets the lines \( \ell_1 \) and \( \ell_2 \) at two different points, then \( \ell \in \Omega_{q}(\Pi) \) (since \( \Pi \cap \ell_4 = \{q\} \)). Else \( \ell \) meets \( \ell_1 \) and \( \ell_2 \) at some point different of \( p \), then \( \ell \subset \langle p, \ell_4 \rangle \). Therefore, \( \mathcal{S} = \Omega_{q}(\Pi) \cup \Omega_{p}(\langle p, \ell_4 \rangle) \) and it can be identified with two projective lines having a common point (just a cross!). On the other hand, since \( P_1, P_2 \) and \( P \) lies on the line \( \Omega_{p}(\Pi) \) and \( P_4 \not\in \Omega_{p}(\Pi) (p \not\in \ell_4) \) we conclude that \( \Lambda \) is a plane in \( \mathbb{P}^5 \) not contained in \( \mathcal{Q} \). So \( \Lambda \cap \mathcal{Q} \) is a conic. Note that the line \( L_{1,2} = \langle P_1, P_2 \rangle \subset \Lambda \cap \mathcal{Q} \) and \( P_4 \not\in L_{1,2} \). Therefore, \( \Lambda \cap \mathcal{Q} \) is the union two lines. In fact, \( \Lambda \cap \mathcal{Q} = L_{1,2} \cup L \) where \( L = \langle P_4, M \rangle \) with \( M = \mathcal{P}(\langle p, q \rangle) \).

Table 4: 2.3 Any Three Lines are non Coplanar and at Least Two Pair of Lines are Coplanar with \( \ell_i \neq \Pi_1 \cap \Pi_2 \forall i \). Assume that \( \ell_1 \cap \ell_2 = \{p\} \) and \( \ell_3 \cap \ell_4 = \{q\} \). Set \( \Pi_1 = \langle \ell_1, \ell_2 \rangle \) and \( \Pi_2 = \langle \ell_3, \ell_4 \rangle \).

</tr>
</tbody>
</table>

2.3.3 Let \( \ell \) be a solution. Next we consider the following two cases.

(i) Assume that \( p \in \ell \). Suppose that \( \ell \) meets the lines \( \ell_3 \) and \( \ell_4 \) at two different points, then \( \ell \subset \Pi_2 \) which implies that \( p \in \Pi_1 \cap \Pi_2 \). But this is impossible, so \( q \not\in \ell \). Therefore \( \ell = \ell_{p,q} \). Similarly, we conclude that \( \ell = \ell_{p,q} \) if \( q \in \ell \).
Now, note that the line \( L_{1,2} = (P_1, P_2) \subseteq \Lambda \cap \mathcal{Q} \) and \( P_i \not\in L_{1,2}, \ i = 3, 4 \). So \( (P_1, P_2, P_3) \) is a plane not contained in \( \mathcal{Q} \) (since \( p \not\in \ell_i \) and \( \ell_i \not\subseteq \Pi_1 \) for \( i = 3, 4 \)). On the other hand, the line \( L_{3,4} = (P_3, P_4) \) is also contained in \( \Lambda \cap \mathcal{Q} \) and we observe that \( L_{1,2} \) and \( L_{3,4} \) are disjoint (since \( L_{1,2} = \Omega_p(\Pi_1) \) and \( L_{3,4} = \Omega_q(\Pi_2) \)), so \( P_4 \) does not belong to the plane \( (P_1, P_2, P_3) \). Therefore, \( \Lambda \) is a 3-plane. Keeping in mind that \( \Lambda \cap \mathcal{Q} \) is a quadric surface containing four non coplanar points and two disjoint lines, we conclude that \( \Lambda \cap \mathcal{Q} \) is a union of two planes or a nonsingular quadric. Suppose that \( \Lambda \cap \mathcal{Q} \) is a union of two planes, say \( \Lambda \cap \mathcal{Q} = \Lambda_1 \cup \Lambda_2 \). Thus we can assume that \( L_{1,2} \subseteq \Lambda_1 \) and \( L_{3,4} \subseteq \Lambda_2 \). Then necessarily \( \Lambda_1 \) it is either \( \Omega_p \) or \( \Omega(\Pi_1) \), and in the same form \( \Lambda_2 \) it is either \( \Omega_q \) or \( \Omega(\Pi_2) \). But in any case, \( \Lambda_1 \cap \Lambda_2 \) will be empty or a point. Therefore, \( \Lambda \cap \mathcal{Q} \) is a nonsingular quadric surface.

</tr>
</tbody>
</table>

#### 2.4.4

Let \( \ell \in \mathcal{Q} \). Here we have two possibilities:

(i) \( p \not\in \ell \). Then \( \ell \cap \ell_1 \neq \ell \cap \ell_2 \) and we have that \( \ell \subseteq \Pi_1 \). Thus \( \ell \cap \ell_3 \subset \Pi_1 \cap \ell_3 = \{q\} \) and \( \ell \cap \ell_4 \subset \Pi_1 \cap \ell_4 = \{r_1\} \). Therefore, \( \ell = \ell_{q, r_1} \) (since \( \ell_4 \not\subseteq \Pi_1 \)).

(ii) \( p \in \ell \). Note that \( \ell \) meets the line \( \ell_3 \) at a point \( p_1 \) (\( p_1 \in \Pi_2 \)) different from \( p \). Thus \( \ell \subset \Pi_2 \). On the other hand \( \ell \cap \ell_4 \subset \Pi_2 \cap \ell_4 = \{r_2\} \). Therefore, \( \ell = \ell_{p, r_2} \).

As in case 2.3.3 we have that \( (P_1, P_2, P_3) \) is a plane not contained in \( \mathcal{Q} \). Since the lines \( L_{1,2} = (P_1, P_2) \) and \( L_{1,3} = (P_1, P_3) \) are contained in \( (P_1, P_2, P_3) \cap \mathcal{Q} \) we conclude that \( (P_1, P_2, P_3) \cap \mathcal{Q} = L_{1,2} \cup L_{1,3} \). So \( P_4 \not\in (P_1, P_2, P_3) \). Therefore, \( \Lambda \) is a 3-plane. Keeping in mind that \( \Lambda \cap \mathcal{Q} \) is a quadric surface containing four non coplanar points, \( \{P_j\} = L_{1,2} \cup L_{1,3} \) and \( L_{1,4} = (P_3, P_4) \not\subseteq \Lambda \cap \mathcal{Q} \) (since \( L_{1,4} \not\subset \mathcal{Q} \)), we conclude that \( \Lambda \cap \mathcal{Q} \) is a union of two planes or a nonsingular quadric. Suppose that \( \Lambda \cap \mathcal{Q} \) is a union of two planes, say \( \Lambda \cap \mathcal{Q} = \Lambda_1 \cup \Lambda_2 \). Thus we can assume that \( L_{1,2} \subseteq \Lambda_1 \). Now, note that \( L_{2,3} \not\subseteq \Lambda \cap \mathcal{Q} \) (since \( L_{2,3} \not\subset \mathcal{Q} \)). So \( P_3 \not\in \Lambda_1 \), which implies \( L_{1,3} \subset \Lambda_2 \). Finally, observe that \( L_{2,4} \) and \( L_{3,4} \) are not contained in \( \Lambda \cap \mathcal{Q} \). Thus \( P_4 \not\in \Lambda_1 \cup \Lambda_2 \). Therefore, \( \Lambda \cap \mathcal{Q} \) is a nonsingular quadric.
Table 6: 2.5 Exactly Two Lines are Coplanar. Assume that $\ell_1$ and $\ell_2$ are contained in the plane $\Pi$, $\ell_1 \cap \ell_2 = \{p\}$. Then $\ell_1 \cap \ell_i = \{p_i\}$ for $i = 3,4$ and $p_3 \neq p_4$. Let $C = \{p, p_3, p_4\}$.

</tbody>
</table>

2.5.3 Let $\ell$ be a solution and consider the following two possibilities.

(i) $\ell \subset \Pi$. Since $\ell \cap \ell_i \subset \Pi \cap \ell_i = \{p_i\}$ then $p_i \in \ell$ for $i = 3,4$. Therefore $\ell = \ell_{p_3,p_4}$.

(ii) $\ell \notin \Pi$. Now having in mind that $\ell \cap \ell_i \neq \emptyset$ for $i = 1,2$ and $\ell \notin \Pi$ we concluded that $p \in \ell$.

On the other hand $\ell \cap \ell_i = \{q_i\} \subset \ell_i \cap \{p_i, \ell_i\}$ for $i = 3,4$. Note that $q_i \neq p$ (since $p \notin \ell_i$ for $i = 3,4$) which implies $\ell = \ell_{p,q_i} \subset \{p, \ell_i\}$ for $i = 3,4$. Therefore, $\ell = (p, \ell_3) \cap (p, \ell_4)$.

Note that $P_1 \notin L_{1,2} = \langle P_1, P_2 \rangle \subset \mathcal{Q}$ for $i = 3,4$. Thus $\langle P_1, P_2, P_3 \rangle$ is a plane not contained in $\mathcal{Q}$ since $p \notin \ell_i \notin \Pi$. Since $L_{1,2} \cup \{P_3\} \subset \langle P_1, P_2, P_3 \rangle \cap \mathcal{Q}$, if $P_4 \in \langle P_1, P_2, P_3 \rangle$ then $P_4 \in L_{1,2}$ or $P_4 \notin L_{1,2}$ because $\ell_4 \notin \Pi$. Moreover, $P_4 \notin L$ since $\ell_4 \cap \ell_3 = \emptyset$. Thus $\Lambda$ is a 3-plane. Keeping in mind that $\Lambda \cap \mathcal{Q}$ is a quadric surface containing four non coplanar points and $L_{1,3}$ is not contained in $\Lambda \cap \mathcal{Q}$, we conclude that $\Lambda \cap \mathcal{Q}$ is a union of two planes or a nonsingular quadric. Suppose that $\Lambda \cap \mathcal{Q}$ is a union of two planes, say $\Lambda \cap \mathcal{Q} = \Lambda_1 \cup \Lambda_2$. Thus we can assume that $L_{1,2} \subset \Lambda_1$. Next, note that $L_{2,3} \notin \Lambda \cap \mathcal{Q}$ (since $L_{2,3} \notin \mathcal{Q}$). So $P_3 \notin \Lambda_1$, which implies $L_{1,3} \subset \Lambda_2$. Now, since $P_4 \in \Lambda_1 \cup \Lambda_2$ we conclude that $L_{2,4}$ and $L_{3,4}$ are contained in $\Lambda \cap \mathcal{Q}$ which it is impossible since $\ell_4 \cap \ell_i = \emptyset$, $i = 2,3$. Therefore, $\Lambda \cap \mathcal{Q}$ is a nonsingular quadric surface.
4.3. No Pair of Lines is Coplanar

Let $Q$ be a nonsingular quadric surface in $\mathbb{P}^3$ containing $\ell_1$, $\ell_2$, and $\ell_3$ (as stated in Lemma 2). Since $\ell_i \cap \ell_j = \emptyset$ for $1 \leq i < j \leq 3$ then they belong to the same family of lines in $Q$ (cf. Lemma 1). So we will assume that $\ell_1$, $\ell_2$, and $\ell_3$ belong to the family $\mathcal{L}$.

Note that any solution $\ell \in \mathcal{S}$ meets the line $\ell_i$ at a point $p_i \in \ell_i \subset Q$ for $i = 1, 2, 3$. Since this three points $p_1$, $p_2$, and $p_3$ are different and belong to $\ell_i \cap Q$. Then follows from Proposition 2 that $\ell \subset Q$, which implies that $\ell \in \mathcal{M}$. Therefore any solution belong to the family $\mathcal{M}$.

In order to determine the set of solutions $\mathcal{S}$ and the linear space $\Lambda$, we will consider the following two subcases.

3.1 $\ell_4 \subset Q$. In this case $\ell_1$, $\ell_2$, $\ell_3$, and $\ell_4$ belong to the same family $\mathcal{L}$ (since $\ell_4$ if disjoint to the others three). Therefore $\mathcal{S} = \mathcal{M}$.

Now, since the line $L_{i,j} = \langle P_i, P_j \rangle \notin \mathcal{Q}$ for $1 \leq i < j \leq 3$, we conclude from Proposition 6 that $\langle P_1, P_2, P_3 \rangle$ is a plane not contained in $\mathcal{Q}$. But, from Remark 1 we conclude that $\langle P_1, P_2, P_3 \rangle \cap \mathcal{L} = \mathcal{P}(\mathcal{L})$. Consequently, $\Lambda = \langle P_1, P_2, P_3 \rangle$ (keep in mind that $P_4 \in \mathcal{P}(\mathcal{L})$ too) and $\Lambda \cap \mathcal{Q}$ is a nonsingular conic.

3.2 $\ell_4 \notin Q$. In this case follows from Proposition 2 that $\ell_4 \cap Q$ is non empty and $\ell_4 \cap Q = \{x, y\}$ (with $x$ and $y$ do not necessarily distinct). Let $M_x$ and $M_y$ be the unique lines in the family $\mathcal{M}$ passing through $x$ and $y$, respectively (cf. (4) in Lemma 1). Indeed $M_x$ and $M_y$ are solutions (in fact, if $p \in \{x, y\}$ then $M_p \cap \ell_i$ is non empty for $i = 1, 2, 3$ because $\ell_i \in \mathcal{L}$ and $M_p \cap \ell_4 = \{p\}$). Now, we will show that $M_x$ and $M_y$ are the unique solutions. Let $\ell \in \mathcal{M}$ be a solution, then $\ell \cap \ell_4 \subset Q \cap \ell_4 = \{x, y\}$ which implies that $x \in \ell$ or $y \in \ell$. Therefore follows from (4) in the Lemma 1 that $\ell = M_x$ or $\ell = M_y$.

Again, since the line $L_{i,j} = \langle P_i, P_j \rangle \notin \mathcal{Q}$ for $1 \leq i < j \leq 3$, we conclude that $\langle P_1, P_2, P_3 \rangle$ is a plane not contained in $\mathcal{Q}$ and $\langle P_1, P_2, P_3 \rangle \cap \mathcal{L}$ is a nonsingular conic. On the other hand, the condition $\ell_4 \notin Q$ implies that $\ell_4 \notin \mathcal{L}$. So, we are left to conclude that $P_4 \notin \langle P_1, P_2, P_3 \rangle$. Thus $\Lambda$ is a 3-plane in $\mathbb{P}^3$. One more time, since $\Lambda \cap \mathcal{Q}$ is a quadric surface containing four non coplanar points and, the line $L_{i,j} \notin \mathcal{Q}$ for $1 \leq i < j \leq 3$, we conclude that $\Lambda \cap \mathcal{Q}$ is a quadric cone or a nonsingular quadric surface. In fact, since $\ell_4 \notin Q$, it must be either: tangent or secant to the surface $Q$. 
Assume that $\ell_4$ is tangent to $Q$. Let $x \in \ell_4 \cap Q$ be the tangent point. Let $M_x \in \mathcal{M}$ and $L_x \in \mathcal{L}$ be the (only) lines in $Q$ passing through $x$. It is verified that $\ell_4 \subset \mathcal{T}_xQ = \langle M_x, L_x \rangle$. Therefore, $\ell_4 \in \Omega_x(\mathcal{T}_xQ)$. Set $M = \mathcal{P}(M_x), L = \mathcal{P}(L_x) \in \mathcal{L}$. Thus $L$ belong to the conic $\langle p_i, p_2, p_3 \rangle \cap \mathcal{L} = \mathcal{P}(\mathcal{L})$. Moreover $M \in \langle L, p_4 \rangle \subset \Lambda \cap \mathcal{L}$ (since, $x \in \ell_4 \subset \langle M_x, L_x \rangle$). On the other hand the lines $L_i = \langle M_i, p_i \rangle \subset \Lambda \cap \mathcal{L}$, $i = 1, \ldots, 4$. Therefore, $\Lambda \cap \mathcal{L}$ is a quadric cone.

Thus we have proved the following Theorem.

**Theorem 1.** Given four lines $\ell_1$, $\ell_2$, $\ell_3$, $\ell_4$ in $\mathbb{P}^3$. Set

$$\mathcal{F} = \{\ell \in \mathcal{G}_1(\mathbb{P}^3) \mid \ell \cap \ell_i \neq \emptyset \text{ for } 1 \leq i \leq 4\}.$$

Let $P_i$ $(i = 1, \ldots, 4)$ be the image of $\ell_i$ in the Plücker’s quadric $\mathcal{Q} \subset \mathbb{P}^5$ under the Plücker embedding $\mathcal{P}$ (in (1)). Set $\Lambda = \langle p_1, \ldots, p_4 \rangle$ be the linear span of those four points in $\mathbb{P}^5$. Then the cardinal of the set $\mathcal{F}$ is either 1, 2 or infinite. Moreover we have.

(i) $\#S = 2$ if and only if $\Lambda$ is a 3-plane and $\Lambda \cap \mathcal{L}$ is a smooth quadric.

(ii) $\#S = 1$ if and only if $\Lambda$ is a 3-plane and $\Lambda \cap \mathcal{L}$ is a quadric cone.

(iii) If $\#S = \infty$ then

(a) $S$ is a line if and only if $\Lambda$ is a 3-plane and $\Lambda \cap \mathcal{L}$ is a union of two planes.

(b) $S$ is a conic if and only if $\Lambda$ is a plane and $\Lambda \cap \mathcal{L}$ is a nonsingular conic.

(c) $S$ is a reduced and reducible conic if and only if $\Lambda$ is a plane and $\Lambda \cap \mathcal{L}$ is a reduced and reducible conic.

(d) $S$ is a plane if and only if $\Lambda$ is a plane in $\mathcal{L}$.

(e) $S$ is a union of two distinct planes if and only if $\Lambda$ is a line in $\mathcal{L}$.

In terms of the lines position Theorem 1 tell us:

\[
\#S = 2 \iff \begin{cases} 
\n \cap_{i=1}^4 \ell_i = \emptyset \text{ and any three lines are non coplanar.} \\
(i) & \ell_1 \cap \ell_2 = \{p\}, \ell_3 \cap \ell_4 = \{q\} \text{ with } p \neq q \text{ and } p \notin \Pi_1 \cap \Pi_2 \neq q, \text{ if } \Pi_1 = \langle \ell_1, \ell_2 \rangle, \Pi_2 = \langle \ell_3, \ell_4 \rangle. \\
(ii) & \ell_1 \cap \ell_2 = \{p\}, \ell_1 \cap \ell_3 = \{q\} \text{ with } p \neq q. \text{ If } \Pi_i = \langle \ell_i, \ell_{i+1} \rangle \text{ for } i = 1, 2, \text{ then it is verified that } \Pi_i \cap \ell_4 = \{r_i\} \text{ for } i = 1, 2 \text{ and } r_1 \neq r_2. \\
(iii) & \ell_1 \cap \ell_2 = \{p\}. \text{ If } \Pi = \langle \ell_1, \ell_2 \rangle \text{ then it is verified for } i = 3, 4 \text{ that } \Pi \cap \ell_i = \{r_i\} \text{, } r_3 \neq r_4 \text{ and } p \notin \langle r_3, r_4 \rangle. \\
\n\bullet & \text{No pair of lines is coplanar.} \\
(iv) & \text{The non singular quadric surface } Q \subset \mathbb{P}^3 \text{ containing } \ell_1, \ell_2 \text{ and } \ell_3, \text{ meets } \ell_4 \text{ exactly in two distinct points.}
\end{cases}
\]
Note that (i), (ii) and (iii) above correspond to subcases 2.3.3, 2.4.4 and 2.5.3 in subsection 4.2. Already (iv) corresponds to subcase 3.2 in subsection 4.3.

\[ \#S = 1 \iff \begin{cases} \cap_{i=1}^4 \ell_i = \emptyset \text{ and any three lines are non coplanar.} \\
(\alpha) \quad \ell_1 \cap \ell_2 = \{p\}, \ell_1 \cap \ell_3 = \{q\} \text{ with } p \neq q. \text{ If } \Pi_i = \langle \ell_1, \ell_{i+1} \rangle \text{ for } i = 1, 2, \text{ then it is verified that } \Pi_i \cap \ell_4 = \{r_i\} \text{ for } i = 1, 2. \text{ with } r_1 = r_2 \text{ and } \#\{p, q, r_1\} = 3. \\
(\beta) \quad \ell_1 \cap \ell_2 = \{p\}. \text{ If } \Pi = \langle \ell_1, \ell_2 \rangle \text{ then it is verified for } i = 3, 4 \text{ that } \Pi \cap \ell_i = \{r_i\}, r_3 \neq r_4, p \in \{r_3, r_4\} \text{ and } p \neq r_i. \\
\bullet \quad \text{No pair of lines is coplanar.} \\
(\gamma) \quad \text{The non singular quadric surface } Q \subset \mathbb{P}^3 \text{ containing } \ell_1, \ell_2 \text{ and } \ell_3, \text{ meets } \ell_4 \text{ exactly in one point.} \end{cases} \]

Note that (\alpha) and (\beta) above correspond to subcases 2.4.3 and 2.5.2 in subsection 4.2. Already (\gamma) correspond to subcase 3.2 in subsection 4.3.

ACKNOWLEDGEMENTS The first author wishes to express her gratitude to I. Vainsencher (DM-UFMG) for a helpful conversation about the subject of this paper.
